

Conclusion on IP's Testing Framework

Based on the information given my reading is that IP set up an experiment with a control and treatment group where the treatment group outperformed the control group in revenue by 15%.

Based on some simple analysis this does not seem to be the case.

Here are my results:

```
Count  IS_TREATMENT_FLAG
False      17380
True       17554
Name: REVENUE, dtype: int64
```

```
Sum  IS_TREATMENT_FLAG
False    1.376996e+06
True     1.390072e+06
Name: REVENUE, dtype: float64
```

```
Average  IS_TREATMENT_FLAG
False      79.228742
True       79.188338
Name: REVENUE, dtype: float64
```

It looks like the treatment and control groups performed almost identically. Sure it's true that overall the Treatment group had more revenue than the control group, but as we can see that was also because the treatment group had more data points.
